5 mistakes that cost you muscle on GLP-1 medicines

On semaglutide, tirzepatide or similar? In the big trials, roughly a quarter to around 40% of the weight lost was lean mass. These five habits make it worse — and each has a simple fix.

1

Eating as little as possible

The medicine already lowers your appetite. Very low intake makes it harder to keep muscle and leaves you tired and dizzy.

Fix: eat by the clock every 3–4 hours, to comfortable fullness.

2

Too little protein

Less food usually means less protein. A 2025 joint advisory on GLP-1 nutrition suggests a simple range of about 80–120 g a day (more conservative with kidney disease — ask your doctor).

Fix: about 25–30 g of protein at each main meal, eaten first.

3

Only doing cardio — or nothing

Walking is great for health, but muscle needs resistance. The same advisory recommends strength training at least 3 times a week.

Fix: 20 minutes at home — sit-to-stand, wall push-ups, bridges, backpack rows.

4

Not drinking enough

Smaller appetite often means less fluid too; with nausea or diarrhoea, dehydration can follow.

Fix: 6–8 glasses a day (NHS), sipped between meals; more if you're unwell.

5

Only watching the scale

Weight can fall while strength drops. That's not the goal.

Fix: every 4 weeks, count how many times you can stand up from a chair in 30 seconds. If it drops, review protein and training — and talk to your doctor.

Want the full plan? Protein targets, a 7-day meal plan, a 12-week home routine, a protein calculator and a printable tracker: **Protein & Muscle on GLP-1 — £9.99**. Free catalog of 200+ peptides: **pepsafe.info**
